More about the difference between the two formats, see "How to use the yaw, pitch and roll information in images linked with PTGui Pro". An important change that will impact the way you will process your data is the introduction of "justification". When importing PTGui Pro files, PTGui Pro automatically scans all images and calculates the justifications for each one. This calculation determines the orientations of the images when they are not aligned with the way they are displayed in PTGui Pro, making it possible to get rid of the grey areas around the image. What is justification? The "justification" of an image is a list of the rotations in degrees that you need to apply on the original image in order to get the original view angle in the browser. If you link images in PTGui Pro 10, your images will not get these rotations automatically, and you will have to manually enter them when you export the image. If you link images in PTGui Pro 11, the images will automatically be rotated to fit the browser window's view, and will have their "justification" set to 0 degrees. This means that the images will be aligned with the way they are displayed in the browser. To answer a common question: no, you don't need to rotate all the images in your linked directory if you are linking the images yourself. You just need to apply the adjustments manually. This means that you can have several sets of linked images: one that is aligned with the browser view, and a second one that is aligned with the grid view. Why is the justification feature new in PTGui Pro 11? There are several good reasons for having this new functionality. The first one is to be able to process linked images at the same time as they are imported in PTGui Pro. If you do that, you can filter the images at the same time as you are selecting them. This means that it is much easier to select an image that is not in the right view angle. The second reason is that once the justification has been calculated, it is automatically saved with the images. If you have linked images with different views, you can process your data with one set of images and a different set of linked images to keep the distinction. You can then use the " 82157476af
